

R Tutorial :-

Basic computations :

1. Calculator-

For just practice run the following in R -

(5+9)*5/80-23

sin(100)

exp(5)

log(9), returns the natural logarithm of 9

log10(2), returns logarithm of 2 to the base 10

abs(-94) , abs gives the absolute value

sqrt(81)

54%%9 , “y%%x” gives the remainder of y/x, here returns 6

ceiling(4.5) , ceiling function round ups to the next larger integer, here it returns 5

floor(4.5), floor function rounds down to next smaller integer, here it returns 4

trunc(5.9), returns the integer part of the number, here returns 5

round(4.2689,digits=3), returns the given number rounded up to the 3 digits, here returns 4.27

2. Variables:

We can assign a variable to any vector as given below:

x=c(4,5,4,9,8,6,9,3)

ans.- [1] 4 5 4 9 8 6 9 3

Run the following:-

x=c(4,2,8,9,7)

length(x), gives the number of elements in the vector.

x[1:3], returns the elements in the position starting from 1 to 3, here find if it is giving the answer correctly.

x[x>4], returns the elements of x which are greater than 4(check)

which(x>4), returns the position of the elements of x which are greater than 4.

3. Generating sequences :-

seq(x,y,by=z) returns a sequence starting with value x, ending at y with increment z.

Perform **seq(1,40,3)**, **seq(1,40,5)**, **seq(10)**, **seq(1:50)** and check what it gives.

Run **seq(1:50,5)**. What do you get? Now do you understand what is **seq(x : y)** actually gives?

Perform **seq(1:50)**, **seq(40:50)**, **seq(39:50)**, **seq(38:50)**, **seq(21:50)**. You will better understand now.

seq(x : y) returns a sequence starting from 1 with length **abs(y-x+1)**.

Perform **seq(19:50)** and **seq(50:19)**. Do you get it?

rep(x,z) returns the value x repeated z times. Run **rep(4,6)**, **rep(4.23,50)**.

Run the following -

x=seq(1:3)

y=rep(x,5)

z=rep(x,each=4)

See what it returns. Do you understand?

4. Accumulating data :-

run the following in R -

x=c(4,25,1,8,90,6,54,75,6)

x1=4*x/5+log(x)

x2=sin(x)+cos(x1)

```
x3= x2%%2-abs(x2-x1)
y=data.frame(x,x1,x2,x3)
y
```

Do you get all the variables and there corresponding values accumulated in a table format?

Some more basic commands and basic stats:-

Run the following in console:-

```
x=c(45,52,65,24,89,75,64,23,56,51,57,58,62,60,67,95,34)
```

```
x
```

```
sum(x)
```

```
mean(x)
```

```
sum(x[x>mean(x)])
```

```
sum(x[x%%2==0])
```

```
var(x) , returns variance of x
```

```
sd(x) , returns standard deviation of x
```

```
sort(x), returns sorted array of x in increasing order.
```

```
min(x)
```

```
max(x)
```

```
quantile(x)
```

```
IQR(x), returns inter quartile range of x
```

```
scale(x) , returns standardised x, i.e., (x-mean(x))/sd(x).
```

```
summary(x)
```

You get it. Isn't it right?

You can perform any function you want. Just for learning purpose play with commands.

Graph plotting:-

plot(v,z) , returns a scatterplot of z vs v, z on y-axis and v on x-axis.

There are many arguments and parameters which can be used inside and outside plot to improve the graph. Run the following:-

```
x=seq(-pi,pi,pi/10)
```

```
y=sin(x)
```

```
plot(x,y)
```

now run- **plot(x,y,type='b',main='sine curve')**

see the difference?

Now find the function of **type** and **main** in the plotting(what they do in the plotting).

Search **par** and read it for once. Try to understand the parameters which can be used.

Use of par in plotting:-

run the following-

```
x=seq(1:30)
```

```
y=x*sin(x)
```

```
plot(x,y,type='b',xaxt='n',main='sine curve')
```

```
axis(1,at=x, labels=x, las=2)
```

Find in **par** what work '**axis**', '**xaxt**' and '**las**' do.

Run the following:-

```
illiteracy.1991=c(1010456,3948251,1636908,1154360,36833351,18857757,14366758,10221940,1788537)
```

```
illiteracy.2001=c(826595,3636084,1405351,1329783,36504260,21169173,13234798,959564)
```

0,1770311)

```
states=c("Himachal Pradesh","Punjab","Uttaranchal","Delhi","Uttar  
pradesh","Bihar","West Bengal","Karnataka","Kerala")
```

```
percent.decrease=((illiteracy.91-illiteracy.01)*100)/illiteracy.91
```

```
percent.decrease
```

```
barplot(percent.decrease, names.arg=states)
```

Now search and read **barplot**. Try to improve the graph by giving title to the graph, x and y labels etc.

Run the following:-

```
years=seq(1977,1981)
```

```
arts=c(1783,2057,2096,2252,2267)
```

```
com=c(590,650,723,848,900)
```

```
sci=c(391,478,438,394,554)
```

```
law=c(400,552,640,689,926)
```

```
subjects=rbind(arts,com,sci,law)
```

```
subjects
```

```
barplot(subjects,beside=FALSE,legend=rownames(subjects),
```

```
main=" Number of students in differnt faculties over
```

```
years",names.arg=years,ylim=c(0,3500),xlab="Years",ylab="number of students")
```

Find out the function of **beside**,**legend** used in barplot.

Check what happens when you use **beside=FALSE**.

Run the following:

```
years=c(1951,1957,1962,1967,1972,1977,1980,1984,1989,1991,1996,1999,2004,2009)
```

```
westbengal=c(7613,10440,10038,13370,13667,15133,21035,25905,32200,31761,37677,3713  
4,37221,42285)
```

```
maharashtra=c(11528,16760,11721,14391,14391,17404,19018,22451,28256,23708,28979,3  
2096,34263,36963)
```

```
rajasthan=c(3626,4649,5415,7095,7158,8673,9709,11465,14594,12596,13188,17927,17346,  
17906)
```

```
karnataka=c(2824,5798,6733,8044,7917,10596,11289,13857,19320,15807,19155,21488,251  
39,24544)
```

```
voters=cbind(westbengal,maharashtra,rajasthan,karnataka)
```

```
matplot(years,voters,type="l",lty=c(1,3,5,6),main="number of voters for some states of  
India over 1951-2009")
```

```
legend("topleft",legend=c("westbengal","maharashtra","rajasthan","karnataka"),lty=c(  
1,3,5,6), bty='n', cex=.75)
```

Read **matplot** in help.

Linear Algebra:-

Run the following commands:-

```
A=matrix(c(1,5,-4,2,-1,0),nrow=2,ncol=3,byrow=TRUE)
```

```
A
```

Find out why we use **byrow=TRUE** (search help matrix).

```
B=matrix(c(6,0,7,-3,-2,2),nrow=2,ncol=3,byrow=TRUE)
```

```
B
```

```
C=matrix(c(1,4,3,-5,-2,1,3,9,-2),nrow=3,ncol=3,byrow=TRUE)
```

```
C
```

check what happens when you perform the following commands:-

`C[1,]` (does it return the 1st row of C?)

`B[,2]` (does it return the 2nd row of B?)

`D=C[-1,-3]`

`D` (does it returns C by deleting it's 1st row and 3rd column?)

`2*A+B`

`5*A-3*B`

`diag(5)`

`diag(c(2,5,4,7))`

`C%*%diag(3)`. What do you get? *%*% is used for matrix multiplications.*

`E=C%*%C+5*diag(3)`

`E`

`F=A%*%C`

`F`

`nrow(F)`

`ncol(F)`

`t(C)`

`M=(C+t(C))/2` (is it a symmetric matrix?)

`N=(C-t(C))/2` (is it a skew symmetric matrix?)

`det(C)`

`rankMatrix(C)`

do you get the rank of the matrix C from the above command?

Run-

`library(Matrix)`

`rankMatrix(C)`

Now you should get the rank.

`eigen(C)`, returns the eigen values and eigen vectors.

Revisit system of linear equations. Consider the following -
 $Ax=b$.

Implies $x = \text{inverse}(A)*b$

and we know $A*\text{inverse}(A)=I$

Now read **solve** in **search help**.

Run-

`solve(A)`

Does it give the inverse of A?

Hence to find inverse of any matrix M use **`solve(M)`**.

Solve the following system of linear equations:-

$$2a+5b-c-d+3e=12$$

$$a-b+c+d+e=3$$

$$2a+b+3c-4d+2e=19$$

$$3a-2b-4c+d-e=-6$$

$$a+2b+2c-3d-3e=8$$

Hint:- write the above in the form of $Ax=b$ and use `solve(A,b)`

Random number generation:-

Try searching for “how to generate random numbers from a given probability distribution in R” in Google.

Try generating random numbers from :

a) binomial distribution,

b) normal distribution,

c) uniform distribution.

You will get functions like `rbinom`, `dbinom`, `pbinom`, `qbinom` for binomial. Similarly for other distributions you can find.

You can search it in R studio itself. Read all the functions. In the upcoming exercises it will be needed.

Programs for practice:-

1. Write a program to return the numbers between 50 and 5000 whose square roots are divisible by 2.
2. a. Create a plot of function $\exp(-x) \cdot \cos(6\pi x)$, where x takes on data points over interval $(0,1)$ with increment .5
b. On the same figure, plot functions $\exp(-x)$ and $-\exp(-x)$. Give different colors/patterns for each curve.
